

A software factory your team owns and runs

AI develops, tests, and deploys through defined procedures.
User feedback informs the next improvement.

ROBOCO builds this production system with your team and transfers the capability to run and improve it. People set the goals and quality criteria, and make the important decisions.

Build what you intend

Define expected behavior and success criteria, then verify the result.

Keep improving

Learn from real use to refine both the product and its intent.

Own the capability

Your team retains the knowledge, development system, and control.

People set the direction. AI carries the workflow forward.

An AI-native process grounded in modern software engineering connects intent, release, and improvement. Domain experts and developers work together, with security and cost criteria applied throughout.

What people do

Understand customer problems and set goals and quality criteria. Decide priorities and important changes, and check whether results match the intent.

What AI does

Implement, test, and deploy within defined permissions and verification procedures. Report outcomes and evidence for decisions, and carry feedback into the next task.

1. Define intent

Clarify the problem and the expected outcome.

2. Build with AI

Use domain knowledge and development standards to create features.

3. Verify and deploy

Check quality and release through agreed procedures.

4. Observe and improve

Use real outcomes to refine the next intent and features.

Feed what you learn back into intent, and repeat.

Three foundations for continuous delivery

Intent and knowledge

Organize requirements, domain knowledge, and decision rationale as assets people and AI can use together.

Pipelines and harnesses

Connect recurring steps with AI execution and verification environments. Incorporate security, cost, review, and approval criteria.

Cloud-native infrastructure

Design deployment and operations so teams can provision and change the environments they need.

ROBOCO combines **experience at global technology companies, AI expertise, and capability transfer**. Our goal is a team that understands its production system and can improve it independently.

Start with real work.

Build a system your team can run.

For companies bringing outsourced development in-house, businesses pursuing digital or AI transformation, and digital-native teams seeking faster, more accurate delivery.

01

Practical pilot

Validate through real work

Select one task or feature and define intent and success criteria. Build a development, verification, and deployment workflow together. Your team makes the next improvement.

What remains: A working result, reusable workflow, practical experience, and a plan for the next stage.

02

Software factory setup

Make the process repeatable

Extend the validated workflow across the team. Establish cloud infrastructure, pipelines, harnesses, and operating standards, and transfer the capability to use them.

What remains: Environments and knowledge you own, production procedures, and the ability to operate them.

03

Operational improvement

Improve the product and system

Turn user feedback and operating results into the next improvement. Review security, cost, and verification criteria. Evaluate new AI capabilities through real work before adoption.

What remains: Continuous improvement practices, accumulated verification criteria, and the ability to adapt.

Training and advisory are part of every stage. Hands-on learning and joint development enable domain experts, including those without a development background, to build and improve features themselves.

Specialist service: certification and compliance consulting

Support for K-FSI, ISO 27001, and K-ISMS preparation: criteria analysis, evidence management, response drafting, and operational capability transfer. [Explore this service](#)

Begin with an initial consultation

Select a real piece of work and agree on the pilot's **scope, timeline, cost, and success criteria** before starting.

Building capability with our customers

Anonymous examples of helping customers build, make decisions, and operate their own systems.

Business software / Development capability

From outsourced development to building in-house

After a prolonged outsourcing effort failed to deliver its intended solution, a company **launched a prototype within one month with ROBOCO**. We established AI-native development and verification processes so domain experts with no prior development background could build and improve features themselves. A small team **continues its transition toward a software factory with us**.

Software company / Organizational AI adoption

Turn training into adoption plans for each team

We connected developer and leadership education on **AI adoption and modern software engineering with practical workshops**. We reviewed the resulting team plans for feasibility, completeness, risk, and shared learning, considering each team's environment and constraints.

Global SaaS company / AI and compliance advisory

Extend AI consulting into assessment preparation

Our work expanded from AI consulting to **preparation for a compliance assessment for entry into a regulated market**. We supported interpretation of criteria, evidence organization, and response drafting, helping the customer manage its own information and working knowledge.

Information that identifies clients is omitted. One month was the first client's time to a prototype. Each project's scope and timeline are agreed individually.

We adapt public methods such as **Intent Engineering, VDLC, and VAF** to each customer's needs, connecting training, joint development, and operational support. [Explore our services and adoption journey](#)

Start with your own business needs

Design and build your software factory with us.
